

Power Automate: AutoDiscount_New

Implementation Guide & Technical Documentation

1. Objective

This flow automates the calculation of a 10% discount for products stored in a Microsoft Dataverse table. It runs on a scheduled basis, processes every row, and updates the final price automatically.

2. Flow Configuration Steps

1 Trigger: Recurrence

Field	Value
Interval	10
Frequency	Minute

2 Action: List rows

Target Table: myProductDiscounts

3 Control: Apply to each

Input: value (from List rows)

3. Technical Logic (Inside Loop)

A. Convert Original Price

Action Name: **OriginalPriceNumber** (Compose)

```
float(items('Apply_to_each')?['cr614_originalprice'])
```

B. Calculate Discount (10%)

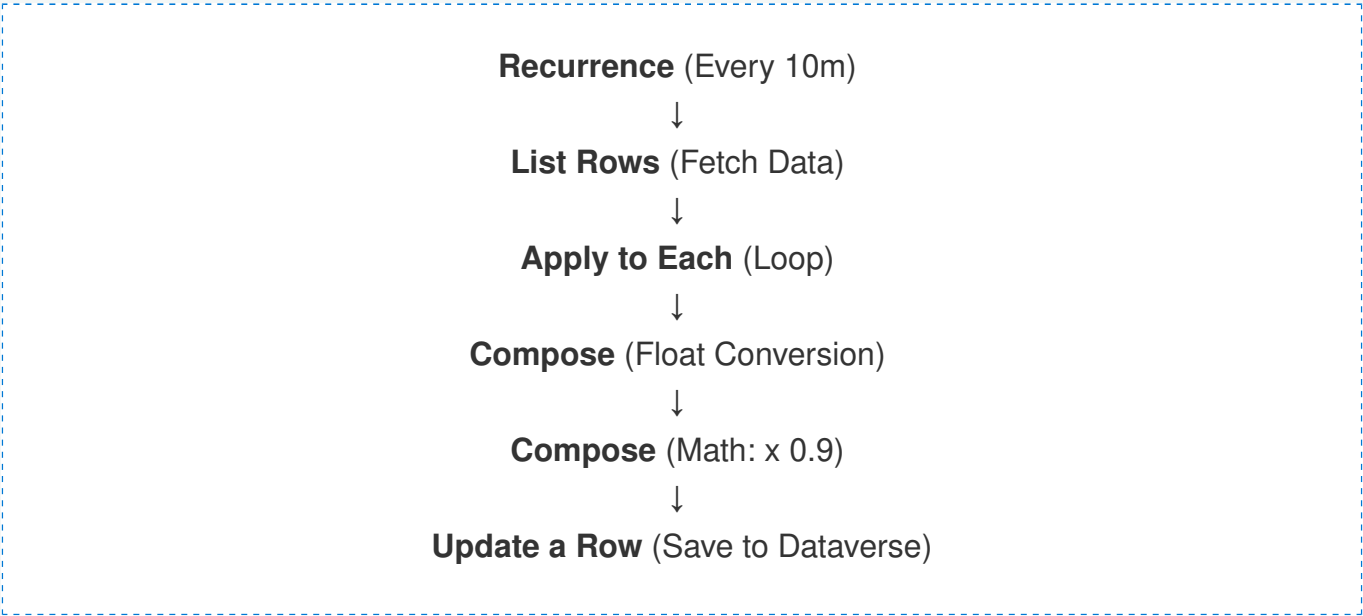

Action Name: **FinalPriceCalculated** (Compose)

```
mul(outputs('OriginalPriceNumber'), 0.9)
```

C. Update Dataverse Row

Field	Expression / Value
Table Name	myProductDiscounts
Row ID	<i>items('Apply_to_each')?['cr614_myproductdiscountsid']</i>
FinalPrice	<i>outputs('FinalPriceCalculated')</i>

4. Visual Flow Summary

CRITICAL NOTE: Always use the unique **GUID** (Primary Key) for the Row ID field in the "Update a row" action. Using a custom Product ID will cause the flow to fail.

5. Expected Results

Product	Original Price	Status	Final Price (Updated)
Item 1003	1000.00	Processed	900.00
Item 1004	50.00	Processed	45.00
